1 Overview

Reconnaissance (recon for short) is a key stage within the Advanced Attackers kill chain. Once attackers have breached a single end-point, they need to discover their next targets within the victim's corporate network, most notably privileged users.

Once attackers had "zoomed in" on target users, they need to find out the computers they had logon to, in order to propagate to them and compromise their credentials. Applying the SMB Session enumeration via the NetSessionEnum method against the DC (or other file servers), allows the attackers to get that information. Recently, some frameworks (e.g. BloodHound²) have automated that mapping process.

By default, NetSessionEnum method can be executed by any authenticated user, including network connected users, which effectively means that any domain user is able to execute it remotely.

Since the only current method to modify the default permissions for NetSessionEnum is by manually editing hex registry entry, we wrote the "NetCease" tool, a short PowerShell (PS) script which alters these default permissions. This hardening process should block attackers from easily getting valuable recon information.

² <https://github.com/adaptivethreat/BloodHound>

1 Net Session Enumeration

Net Session Enumeration is a method used to retrieve information about established sessions on a server. Any domain user can query a server for its established sessions and get the following information:

- The name/IP address of the computer.
- The name of the user who established the session.
- The number of seconds the session has been active. (since the query)
- The number of seconds the session has been idle. (since the query)

Since all domain users/computers are updating their Group Policy approximately every 90 minutes, they establish a session to the DC and query for an update. Those sessions are visible to all domain users using the NetSessionEnum on that DC.³

Several widely-available tools implement such query, including the NetSess tool

```
C:\Research\NetSess>NetSess.exe dc1
NetSess V02.00.00cpp Joe Richards <joe@joeware.net> January 2004
Enumerating Host: dc1
Client                User Name                Time                Idle Time
-----
\\\\192.168.0.10      user1                      000:00:13          000:00:00
\\\\192.168.0.4       CLIENT4-PC$              000:01:11          000:01:00
\\\\[::1]             DC1$                      000:00:02          000:00:02
\\\\192.168.0.4       Administrator             000:00:02          000:00:02
Total of 4 entries enumerated
```

Figure 1: NetSess tool result example.

MicrosoftATA⁴ detects the use of such query and alerts the security administrator about it

³<https://microsoft.sharepoint.com/teams/Aorato/Shared%20Documents/Research/NTLM/Revealing%20NTLM%20Authenticated%20User%20using%20NetSess.docx?d=weba80c33af934227b2c1c72203baf64c>

Reconnaissance using SMB Session Enumeration
SMB session enumeration attempts were successfully performed from USER1-PC against DC1, exposing 4 accounts.

Note Share Export to Excel Details Input Open

Session Enumeration

The diagram illustrates a network connection between a client machine labeled 'USER1-PC' and a server machine labeled 'DC1'. A central box titled 'Session Enumeration' is connected to both. Below this box, a list titled 'Exposed Accounts (4)' contains the following entries:

Account Name	IP Address
SECRETS-DB\$	on 192.168.0.210
user1	on 192.168.0.1
APP2\$	on 192.168.0.5
user2	on 192.168.0.5

Recommendations

- Disconnect USER1-PC from the network, or move it into an isolated environment and start a forensics procedure by investigating: unknown processes, services, registry entries, unsigned files, and more
- Verify that all enumerated accounts use a strong password.

Figure 2 MicrosoftATA alert on NetSessionEnum use

2 NetSessionEnum permissions

NetSessionEnum method permissions are controlled by a registry key under the following path:

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\LanmanServer\DefaultSecurity\SrvsvcSessionInfo

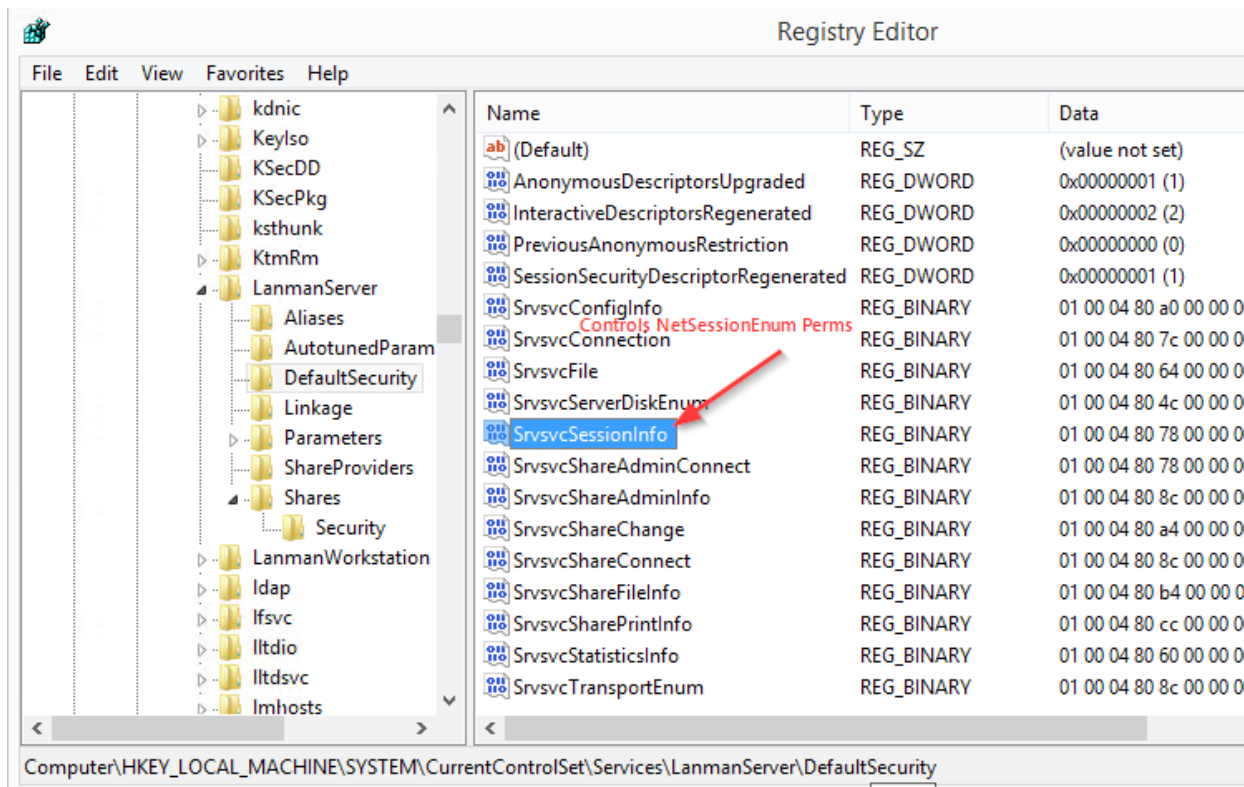

Figure 3 NetSessionEnum DACL in Registry

By default, this binary SrvsvcSessionInfo value is a Discretionary Access Control List (DACL) containing 4 Access Control Entries (ACE) which allows access to any user with at least one of the following characteristics:

- Member of Administrators group (Security Identifier (Sid) S-1-5-32-544)
- Member of Server Operators group (Sid S-1-5-32-549)
- Member of Power Users group (Sid S-1-5-32-547)
- Last but not least Authenticated Users group (Sid S-1-5-11)

By performing a successful network authentication against a domain joined machine, the users (or attackers) obtain the permission to execute NetSessionEnum on that machine, as they got the "Authenticated Users" Sid added to their authentication context.

3 NetCease details

The NetCease script hardens the access to the NetSessionEnum method by removing the execute permission for Authenticated Users group and adding permissions for interactive, service and batch logon sessions.

This will allow any administrator, system operator and power user to remotely call this method, and any interactive/service/batch logon session to call it locally.

Calling NetSess on a hardened machine from remote, using an administrator account:

```
C:\Research\NetSess>whoami
domain1\administrator

C:\Research\NetSess>ipconfig

Windows IP Configuration

Total of 1 entries enumerated
```

Figure 6: User1 (non-admin) successfully calls NetSess locally

4 Using NetCease.ps1

NetCease is simple to use. Run the PowerShell script as administrator on the machine you wish to harden (DC in most cases). In order for the changes to take effect, restart the "Server" service.

Note that hardening NetSession and hindering attackers' ability to abuse it, does not damage defenders' ability to detect the attack, as MicrosoftATA detects failed recon attempts as well

The screenshot shows a Microsoft ATA alert titled "Reconnaissance using SMB Session Enumeration". The alert text states: "SMB session enumeration attempts failed by user1, from CLIENT2-PC against DC1. No accounts were exposed." Below the alert text are icons for "Note", "Share", "Export to Excel", "Details", and "Input", along with an "Open" button.

A blue banner asks: "Is running scanning tools allowed from the computer listed below?". Below this is a diagram showing a flow from "user1" (represented by a profile picture) to "CLIENT2-PC" (represented by a computer icon), which then performs "Session Enumeration" (represented by a document icon) against "DC1" (represented by a server icon).

Below the diagram is a "Computers (1)" section with a search icon. It lists "CLIENT2-PC" with a toggle switch set to "No". There are "Save" and "Cancel" buttons. A message at the bottom of this section reads: "Once saved, this suspicious activity might be dismissed".

At the bottom of the alert, there is a "Recommendations" section with a single bullet point: "Disconnect CLIENT2-PC from the network, or move it into an isolated environment and start a forensics procedure by investigating: unknown processes, services, registry entries, unsigned files, and more".

Figure 7 MicrosoftATA detection of a failed NetSessionEnum recon attempt
